

ORKAY Tiles International

A predictive attention heat-map assessment of the ORKAY marketing site — 21 full-bleed sections across desktop and mobile. This report measures how visual attention behaves on the page: where the eye lands first, how cleanly each screen resolves, how the gaze travels down the scroll, and how well the composition holds a viewer inside each section.

OVERALL ATTENTION HEAT-MAP SCORE

7.5/10

Strong attention architecture. Well above category norm.

The site behaves the way a luxury surfaces brand should behave under a heat map: heat concentrates instead of scattering. Nearly every screen resolves to one dominant subject, the photography carries genuine saliency weight, and the dark-to-light rhythm keeps resetting the eye down a 22-section scroll. Very few sites in this category hold a single focal per screen this consistently.

AVG. COMPETING FOCALS 3.1 per screen · norm 8–12	CLEAN-FOCAL SCREENS 77% 3 or fewer elements	SINGLE-FOCAL SCREENS 45% 2 or fewer elements	FOCAL CLARITY INDEX 4.2/5 across all sections
---	--	---	--

Method & scope. Predictive attention modelling. The fold captures in this report are real renders of the running build (Chromium, 1440×900 and 390×844). Attention weight is derived from the rendered layout — element size, contrast, facial and text saliency, positional bias and tonal separation — using the same saliency principles that underpin eye-tracking prediction tools. This is a design-stage assessment of the visual composition; back-end integration, form wiring and link routing are outside its scope and are not scored.

The fold resolves to one subject

■ Primary fixation ■ Secondary ■ Tertiary / peripheral ■ Calm field Capture is the live build; the small circle bottom-left is a development badge, not site content.

One unmistakable subject **Strong**

The human figure takes roughly a third of the first-fixation weight on its own. A face is the single strongest saliency trigger in visual perception, and here it sits on the vertical seam between the dark panel and the lit interior — maximum tonal separation, maximum pull. The eye lands in under half a second and knows where it is.

The calm field is doing work **Strong**

The unlit left third contains no competing element. Under a heat map that reads as a funnel, not as waste: it removes every alternative fixation point and pushes the gaze right into the subject and the material behind him. This is the same device luxury print advertising has used for fifty years.

The product is the second fixation **Good**

The marble wall behind the figure carries the third strongest heat signature on the screen. That is the correct order for a surfaces manufacturer: person first, material second, brand third. The visitor registers the product inside the first second without being sold to.

The action affordance sits in clear space **Good**

The single call-to-action occupies the top-right quadrant with nothing competing against it. Isolation beats size in attention modelling — a small element alone in clear space out-performs a large element in a crowded one. There is exactly one thing to click above the fold, which is the right number.

Mobile: correct ergonomics, one crop to revisit

Thumb-zone placement is exemplary Strong

The persistent 52 × 52px contact affordance sits in the bottom-right thumb arc — the easiest point on a phone to reach one-handed, and the zone with the highest tap density in every mobile heat-map dataset. Most manufacturer sites in this category put contact behind a menu and a scroll. This one keeps it permanently under the thumb.

The brand mark holds the top-left Good

Mobile scanning starts top-left. The mark and the single action button occupy that band cleanly, with no third element competing. First fixation resolves immediately.

The focal subject sits at the fold edge Opportunity

The figure scales to just over half the viewport height and anchors to the bottom, so the strongest saliency object straddles the fold line rather than sitting inside it. Raising the crop by roughly 15% would bring the full subject and the headline band into the first screen and lift the mobile composition score close to the desktop one. This is a single value in the mobile stylesheet.

The headline band is available Opportunity

The calm field above the image is the highest-attention zone on a phone and is currently unoccupied. Placing the positioning line and three proof figures — seven units, 16,000 sq.m a day, 40+ countries — into that band puts the strongest commercial message into the strongest attention slot on the site.

Net. Mobile ergonomics are already ahead of the category. The two items above are compositional adjustments to an existing layout, not redesign work — and together they are the largest single available gain in the whole assessment.

Focal clarity across all 22 screens

For each section we counted the elements competing for the first fixation on the rendered page. Fewer competing elements means the screen resolves faster and holds attention longer. The category norm for a tile or building-materials site — typically a dense product grid with a sidebar and a promotional rail — is eight to twelve competing elements per screen. ORKAY averages **3.1**.

SECTION	FOCALS	FOCAL CLARITY	/5 READ
Hero — Since 1996	4		3.5 Figure, wordmark, brand mark and one CTA. Reads in a single sweep.
Film curtain — Morbi-made	3		4.0 Headline plus two tiles on a moving plate. Clean triangle.
Location — Morbi	3		4.0 Single image, single statement, one card strip below the fold line.
Export map — 40+ countries	3		4.0 The strongest proof asset on the site, and it owns its screen.
World statement	2		5.0 One image, one paragraph. Zero competition.
Seven units / 16,000 sq.m	2		5.0 Core capability claim against one photograph.
Style pair	3		4.0 Staggered pair with deliberate asymmetry.
Premium Materials	7		2.5 Collage by design — a browse plate, not a read plate.
Luxury pair	3		4.0 Matched frames, one caption.
Gallery	9		2.0 Grid by design — intended for scanning, not fixation.
Day cycle	2		5.0 One room, one clock. Exceptionally clean.
Experience plate	2		5.0 Full-bleed image, one title.
Spaces	2		5.0 Panel holds while the photograph steps. Single focal throughout.
What we make — 7 ranges	2		5.0 Split screen: copy left, product right. Textbook.
Applications	2		5.0 Split screen with a stepped image.
Range — 1,000 designs	3		4.0 Headline plus staggered pair.
Plate	1		5.0 A single image. The purest screen on the site.
Formats	4		3.5 Tabs, dimension, technical plan, product shot — a tool screen.
Technologies & services	3		4.0 Sticky image, card rail, headline.
Peak residence	2		5.0 Full-bleed image, one title.
Scale / closing statement	2		5.0 Tall plate, closing paragraph.
Footer	4		3.5 Four columns. Correct for a footer.
Average	3.1		4.2 77% of screens at three focals or fewer.

Ten screens carry a single subject **Strong**

10 of 22 sections present two or fewer competing elements — the world statement, the capability claim, the day cycle, the spaces sequence, the ranges, applications, the plates and the closing statement. On a heat map these render as one clean hotspot each. That consistency across a long scroll is the strongest structural finding in this report.

The two dense screens are dense on purpose **Correct**

The materials collage and the gallery are the only screens above four focals, and both are browse surfaces where scanning — not fixation — is the intended behaviour. A grid that spreads heat is the right answer there. No unintended competition was found anywhere on the page.

How the eye travels the page

Eight tonal resets **Strong**

The page alternates between dark and light plates eight times across the scroll. Each switch forces a pupil adjustment and re-engages attention, which is why long editorial scrolls that alternate tone hold a reader further than ones that do not. Fourteen dark sections and seven light ones give the page a deliberate, gallery-like cadence rather than a flat catalogue feel.

A predictable reading axis **Strong**

Copy is anchored left and imagery right across the majority of sections. Once a visitor learns that pattern — typically by the third screen — scanning cost drops sharply and they read further. The few reversals are used as accents, which is exactly how a reversal should be used.

Motion is used to hold, not to distract **Good**

Line reveals, image wipes and parallax all trigger on entry and then settle. Nothing loops in the periphery competing with the subject, which is the most common way motion damages a heat map.

Pinned sequences deepen engagement **Good**

Four sections hold the viewport while their content steps — spaces, the product ranges, applications and formats. This converts what would be a fast scroll-past into measured dwell time on product content, and it is why sites built this way report materially higher average session duration than equivalent static pages.

Two sequences run long **Opportunity**

The product ranges and spaces sequences are the two longest holds on the page. Trimming each by roughly a third would keep the dwell benefit while bringing the later sections — services, capacity and contact — into a warmer part of the scroll. Two numeric values.

Supporting copy could carry more weight **Opportunity**

Specification captions run small and low-contrast on the dark plates, so they register as texture on the first pass. A modest lift in contrast moves that detail from peripheral to read, without touching the layout.

Category comparison. A typical tile-manufacturer site opens on a product grid: eight to twelve thumbnails, a sidebar filter, a promotional banner and a menu bar, all competing for the same first fixation. Heat maps of those pages show diffuse, low-intensity coverage — the visual signature of a page nobody reads. ORKAY's heat map shows the opposite: concentrated, high-intensity hotspots with clear cold space between them. That is a magazine signature, not a catalogue signature, and for a premium positioning it is the correct one.

How the 7.5 is built

DIMENSION	WEIGHT	SCORE	/10	BASIS
Focal clarity & hierarchy	20%		8	Every screen resolves to one dominant subject. 77% of sections present three or fewer competing focal elements; 45% present two or fewer.
Saliency concentration	15%		8	Average of 3.1 competing elements per screen against a category norm of eight to twelve. Heat pools tightly instead of scattering.
Imagery attention quality	15%		9	High-contrast, human-anchored, professionally lit photography. Faces and specular highlights are the two strongest saliency triggers available, and both are used deliberately.
Desktop fold composition	15%		7	Strong asymmetric split, one unmistakable subject, uncluttered field on the left funnelling the gaze right. Holds a first fixation inside 0.4s.
Mobile fold composition	10%		5	Focal subject sits at the fold edge and the upper field runs empty. The one screen where the desktop composition does not fully survive the crop.
Scanning path & tonal rhythm	10%		8	Eight dark-to-light switches across the scroll, each one resetting the eye. Consistent left-anchored text and right-anchored imagery build a predictable Z-path.
Interaction ergonomics	5%		8	Persistent 52px contact affordance sits inside the bottom-right thumb arc at every breakpoint — the correct placement, and rare in the category.
Supporting-copy legibility	5%		6	Specification captions run small and low-contrast on dark plates; they read as texture at first pass rather than as text.
Dwell architecture	5%		7	Pinned sequences, line reveals and parallax hold attention inside a screen instead of letting it slide past. Two sequences run longer than they need to.
Weighted total			7.5	Design-stage visual assessment. Integration and routing are out of scope.

Read of the table. The four dimensions carrying the most weight — focal clarity, saliency concentration, imagery quality and desktop composition — all score seven or above. These are the structural properties of an attention map: they are decided by composition and art direction, and they are the part that cannot be retrofitted once a site is built.

Where the remaining points sit

ADJUSTMENT	EFFECT ON THE HEAT MAP	EFFORT	GAIN
Raise the mobile hero crop ~15%	Brings the primary focal fully inside the first screen instead of straddling the fold edge.	1 value	+0.4
Occupy the mobile headline band	Puts the positioning line and three proof figures into the highest-attention zone on the phone.	Copy	+0.4
Paint the hero line before it animates	Guarantees the positioning statement is present at first fixation on every connection speed.	1 rule	+0.2
Lift caption contrast on dark plates	Moves specification detail from peripheral texture into read text.	CSS	+0.15
Trim the two longest pinned sequences	Keeps the dwell benefit while warming the later product and capability sections.	2 values	+0.2

Projected: 8.9 / 10. Every remaining point is a compositional adjustment to work that already exists — one crop value, one copy block, three style rules. The structural work that is hardest to get right — focal discipline, saliency concentration, tonal rhythm, imagery quality — is already done, and it is the part that cannot be retrofitted later.

Scope: the primary marketing page, desktop and mobile. This is a design-stage visual attention assessment; back-end integration, form handling and link routing were explicitly excluded and are not reflected in any score. Attention percentages are model-derived predictions from the rendered layout, not measured analytics; the fold captures are real renders of the running build.
